

Docket No. RSW920030224US1

**METHOD, APPARATUS, AND PROGRAM FOR MINIMIZING INVALID
CACHE NOTIFICATION EVENTS IN A DISTRIBUTED CACHING
ENVIRONMENT**

5 **BACKGROUND OF THE INVENTION**

1. Technical Field:

 The present invention relates to data processing
systems and, in particular, to distributed caching
10 environments. Still more particularly, the present
invention provides a method, apparatus, and program for
minimizing invalid cache notification events in a
distributed caching environment.

15 **2. Description of Related Art:**

 Using two or more computer systems that work
together is referred to as "clustering." Clustering
generally refers to multiple servers that are linked
together in order to handle variable workloads or to
20 provide continued operation in the event one fails. Each
computer may be a multiprocessor system itself. A
cluster of servers provides fault tolerance and/or load
balancing. If one server fails, one or more additional
servers are still available. Load balancing distributes
25 the workload over multiple systems.

 A cache is used to speed up data transfer and may be
either temporary or permanent. A server may cache
information that is frequently accessed. Some content
has a short lifespan. For example, many servers generate
30 dynamic content, which is relevant for a short period of

Docket No. RSW920030224US1

time. These cache entries are assigned a time to live (TTL), which is a time of expiration. Thus, a server must perform cache management to keep the cache entries fresh and relevant.

5 Often, servers in a cluster generate similar data. Therefore, a benefit exists for sharing cache information among clustered servers. In a distributed caching environment, notification events are passed between member servers to synchronize cache entries within the
10 managed cluster's domain. These notification events are used to add or update information in remote caches or to invalidate current information in remote caches.

 If the clocks in the member servers are not synchronized, an incoming event may be unexpectedly
15 discarded. Discarded events can cause poor system-wide performance, because the expected cached information will not be found and must be regenerated. Data integrity problems can also occur due to server clock error by allowing cached objects to live longer than expected.

20 Typically, to solve this problems, customers attempt to have each server's clock synchronized either manually or through external methods. Add-on products that implement a time protocol, such as network time protocol (NTP) or digital time services (DTS), may also be used.
25 However, in a heterogeneous network environment, these methods lack the product-embedded inter-enterprise solution. Tying the solution to the product isolates the distributed caching systems from the problems that arise when no external NTP or DTS external product is employed,
30 enterprises use different external methods for

Docket No. RSW920030224US1

synchronizing clocks, or additional caching nodes are inserted into the network from a new enterprise.

As an example of the problem in the prior art, consider a first server and a second server with
5 synchronized clocks. A cache entry is created by the first server with a TTL of ten minutes. A cache notification event is sent from the first server to the second server. The second server will receive the cache notification event and create the cache entry with a
10 correct TTL.

However, consider an instance where the clock of the first server is four minutes ahead of the clock of the second server. The second server will receive the cache notification event and create the cache entry; however,
15 the cache entry will have only six minutes to live. Thus, the event will be discarded prematurely. This will result in poor system performance, because data must be regenerated sooner than expected.

Now, consider an instance where the clock of the
20 first server is four minutes ahead of the clock of the second server. In this case, the event will live longer than expected in the second server. This will result in data integrity problems, because data may live longer than the relevancy of the data.

Docket No. RSW920030224US1

SUMMARY OF THE INVENTION

The present invention recognizes the disadvantages of the prior art and provides a distributed cache management system that minimizes invalid cache notification events. A cache management system in a sending device processes outgoing cache notification events by adding information about the source server's clock. A cache management system in the receiving device then uses this information to adjust event information once the event is received.

BRIEF DESCRIPTION OF THE DRAWINGS

The novel features believed characteristic of the invention are set forth in the appended claims. The invention itself, however, as well as a preferred mode of use, further objectives and advantages thereof, will best be understood by reference to the following detailed description of an illustrative embodiment when read in conjunction with the accompanying drawings, wherein:

10 **Figure 1** depicts a pictorial representation of a network of data processing systems in which the present invention may be implemented;

Figure 2 is a block diagram of a data processing system that may be implemented as a server in accordance with a preferred embodiment of the present invention;

Figure 3 is a block diagram illustrating an exemplary distributed caching environment in accordance with a preferred embodiment of the present invention;

20 **Figure 4** is a block diagram illustrating a software structure of a computing device in accordance with an exemplary embodiment of the present invention;

Figures 5A-5C illustrate example cache invalidation and update operations in accordance with a preferred embodiment of the present invention;

25 **Figure 6** is a flowchart illustrating the operation of a cache manager in a sending device in accordance with a preferred embodiment of the present invention; and

Figure 7 is a flowchart illustrating the operation of a cache manager in a receiving device in accordance with a preferred embodiment of the present invention.

Docket No. RSW920030224US1

DETAILED DESCRIPTION OF THE PREFERRED EMBODIMENT

With reference now to the figures, **Figure 1** depicts a pictorial representation of a network of data processing systems in which the present invention may be implemented. Network data processing system **100** is a network of computers in which the present invention may be implemented. Network data processing system **100** contains a network **102**, which is the medium used to provide communications links between various devices and computers connected together within network data processing system **100**. Network **102** may include connections, such as wire, wireless communication links, or fiber optic cables.

In the depicted example, servers **104**, **114** are connected to network **102** along with storage unit **106**. In addition, clients **108**, **110**, and **112** are connected to network **102**. These clients **108**, **110**, and **112** may be, for example, personal computers or network computers. In the depicted example, servers **104** and **114** provide data, such as boot files, operating system images, and applications to clients **108-112**. Clients **108**, **110**, and **112** are clients to server **104**. Network data processing system **100** may include additional servers, clients, and other devices not shown.

In accordance with an exemplary embodiment of the present invention, servers **104**, **114** shared cache information in a distributed caching environment. The servers pass notification events between them to synchronize cache entries. These notification events are

Docket No. RSW920030224US1

used to add or update information in the server caches or to invalidate current information in a server's cache.

If the clocks in the servers are not synchronized, an incoming event may be unexpectedly discarded.

5 Discarded events can cause poor system-wide performance, because the expected cached information will not be found and must be regenerated. Data integrity problems can also occur due to server clock error by allowing cached objects to live longer than expected. The window of
10 opportunity for discarding these events is based on a difference in the clocks of the servers.

Thus, in accordance with a preferred embodiment of the present invention a distributed cache management system is provided that minimizes invalid cache
15 notification events. A cache management system in a sending server processes outgoing cache notification events by adding information about the source server's clock. A cache management system in the receiving server then uses this information to adjust event information
20 once the event is received.

The distributed cache management system of the present invention reduces the window of opportunity for failure down to the network transport time (NTT), which is usually in the millisecond range. Because the TTL is
25 usually much greater than the millisecond transport time, the distributed cache management system of the present invention virtually eliminates the problems caused by server clock differences.

In the depicted example, network data processing
30 system 100 is the Internet with network 102 representing a

Docket No. RSW920030224US1

worldwide collection of networks and gateways that use the Transmission Control Protocol/Internet Protocol (TCP/IP) suite of protocols to communicate with one another. At the heart of the Internet is a backbone of high-speed data communication lines between major nodes or host computers, consisting of thousands of commercial, government, educational and other computer systems that route data and messages. Of course, network data processing system 100 also may be implemented as a number of different types of networks, such as for example, an intranet, a local area network (LAN), or a wide area network (WAN). **Figure 1** is intended as an example, and not as an architectural limitation for the present invention.

Referring to **Figure 2**, a block diagram of a data processing system that may be implemented as a server, such as server 104 in **Figure 1**, is depicted in accordance with a preferred embodiment of the present invention. Data processing system 200 may be a symmetric multiprocessor (SMP) system including a plurality of processors 202 and 204 connected to system bus 206. Alternatively, a single processor system may be employed. Also connected to system bus 206 is memory controller/cache 208, which provides an interface to local memory 209. I/O bus bridge 210 is connected to system bus 206 and provides an interface to I/O bus 212. Memory controller/cache 208 and I/O bus bridge 210 may be integrated as depicted.

Peripheral component interconnect (PCI) bus bridge 214 connected to I/O bus 212 provides an interface to PCI local bus 216. A number of modems may be connected to PCI

Docket No. RSW920030224US1

local bus 216. Typical PCI bus implementations will support four PCI expansion slots or add-in connectors. Communications links to clients 108-112 in **Figure 1** may be provided through modem 218 and network adapter 220

5 connected to PCI local bus 216 through add-in connectors.

Additional PCI bus bridges 222 and 224 provide interfaces for additional PCI local buses 226 and 228, from which additional modems or network adapters may be supported. In this manner, data processing system 200
10 allows connections to multiple network computers. A memory-mapped graphics adapter 230 and hard disk 232 may also be connected to I/O bus 212 as depicted, either directly or indirectly.

The data processing system depicted in **Figure 2** may
15 be, for example, an IBM eServer pSeries system, a product of International Business Machines Corporation in Armonk, New York, running the Advanced Interactive Executive (AIX) operating system or LINUX operating system. Those of ordinary skill in the art will appreciate that the
20 hardware depicted in **Figure 2** may vary. For example, other peripheral devices, such as optical disk drives and the like, also may be used in addition to or in place of the hardware depicted. The depicted example is not meant to imply architectural limitations with respect to the
25 present invention.

Figure 3 is a block diagram illustrating an exemplary distributed caching environment in accordance with a preferred embodiment of the present invention. Machine A 310 and Machine B 320 are connected to network
30 302, along with user 1 304 and user 2 306. Machine A

Docket No. RSW920030224US1

includes application server 312, cache manager 314, and cache storage 316. Similarly, machine B includes application server 322, cache manager 324, and cache storage 326.

5 When a user, such as user 1 304, access information in machine A, the application server may generate or retrieve information and return the information to the user. For example, application server 312 may be a Web server that generates dynamic content. The application
10 server 312 may then store the information in cache 316 through cache manager 314.

Machine A and machine B may send cache notification events between them to synchronize cache 316 and cache 326. Thus, when application server 312 stores
15 information in cache 316, cache manager 314 may generate a cache notification event and send this event to cache manager 324 for storage in cache 326. For example, a cache entry may be added to a cache. When content is
20 dynamically created or otherwise time-sensitive, a cache entry may be given an expiration or time to live (TTL). This expiration may be a discrete time or an amount of time relative to the created time.

Subsequently, a user, such as user 2 306, may request the same information from machine B 320. Cache
25 manager 324 may find this information in cache 326 and provide the cached information to application server 322, rather than having the application server generate the information again.

Machine A 310 has a clock 318 and machine B 320 has
30 a clock 328. If the clocks in the servers are not

Docket No. RSW920030224US1

synchronized, the cache notification event may be unexpectedly discarded from cache 326 or allowed to live too long in cache 326. Discarded events can cause poor system-wide performance, because the expected cached
5 information will not be found and must be regenerated. Data integrity problems can also occur due to server clock error by allowing cached objects to live longer than expected.

In accordance with a preferred embodiment of the
10 present invention, the cache manager of the sending machine processes outgoing cache notification events by adding information about the source server's clock. Therefore, when cache manager 314 sends a cache notification event to cache manager 324, it adds
15 information about clock 318 to the event.

A cache management system in the receiving server then uses this information to adjust event information once the event is received. Thus, when cache manager 324 receives a cache notification event from cache manager
20 314, it compares the clock information in the event to the local clock, clock 328. The receiving cache manager then determines a clock delta. The receiving cache manager may then adjust the event, such as, for example, adjusting the TTL of the cache entry, based on the clock
25 delta.

Figure 4 is a block diagram illustrating a software structure of a computing device in accordance with an exemplary embodiment of the present invention. A computing device, such as a server, may include an
30 application server 410, for providing information to

Docket No. RSW920030224US1

clients, and a network layer 420, for communicating with other devices in a network data processing system.

Application server 410 includes application software 412, cache manager 414, and connection manager 416. The
5 application software retrieves or generates data responsive to user requests. The cache manager stores and retrieves information in a cache storage and communicates with other cache managers in the distributed caching environment.

10 In an alternative embodiment, connection manager 416 may be a separate layer or part of network layer 420. Cache manager 414 may also be a separate layer. In an exemplary embodiment, the present invention may be embodied within the cache manager or, alternatively,
15 within the connection manager.

Figures 5A-5C illustrate example cache invalidation and update operations in accordance with a preferred embodiment of the present invention. Server 1 510 includes cache component 512; server 2 520 includes cache
20 component 522; and, server 3 530 includes cache component 532. Server 1, server 2, and server 3 send update events and invalidation events to server X 550, which includes cache component 552.

In the depicted example, the clocks of the servers
25 are not synchronized. For example the server X clock is at 12:00 and the server 1 clock is set at 12:00; however, the server 2 clock is set at 12:02 and the server 3 clock is set at 11:58. Therefore, incoming events at server X 550 may be unexpectedly discarded or allowed to live too
30 long.

Docket No. RSW920030224US1

Figure 5B is a block diagram illustrating cache component **552**. Event auditor **554** receives an invalidation event from server 1 which invalidates a cache entry, an invalidation event from server 2 which
5 invalidates the same cache entry, an update event from server 3 which updates a cache entry with a TTL of 60 seconds, and an update event from server 2 which updates a cache entry with a TTL of 60 seconds. The cache notification events, as shown in event auditor **554**, also
10 include the server clock values (timestamps) indicating the time the events were generated. Cache component **552** also includes core cache **556**.

The cache auditor validates the cache notification event to determine if the event should be honored or
15 discarded. The validation may be an isolated or non-isolated validation. As seen in **Figure 5A**, the clocks of the servers are not synchronized; therefore, the invalidation and update events may result in performance issues or data integrity problems.

20 Turning now to **Figure 5C**, the cache manager of server X processes the clocks **562** from the update events and invalidation events received from server 1, server 2, and server 3, and generates clock deltas **564** for the servers. Cache auditor **552** then adjusts the timestamps
25 in the cache notification events and performs the validation as discussed above. The auditor may then make a correct decision because the notification events have been time corrected.

Figure 6 is a flowchart illustrating the operation
30 of a cache manager in a sending device in accordance with

Docket No. RSW920030224US1

a preferred embodiment of the present invention. The process begins and generates a cache event (step 602). The process then adds a timestamp to the cache event (step 604) and sends the cache event to the receiving
5 device or devices (step 606). Thereafter, the process ends.

Figure 7 is a flowchart illustrating the operation of a cache manager in a receiving device in accordance with a preferred embodiment of the present invention.
10 The process begins and receives a cache event (step 702). The process compares a local clock to the timestamp (step 704) and determines a clock delta (step 706). Then, the process adjusts time information in the cache event based on the clock delta (step 708) and ends.

15 The present invention may also apply to other time-sensitive information in addition to cache information. For example, servers in a cluster may send status information for balancing workloads or for fault tolerance. In any instance where time sensitive
20 information is passed among connected devices, the techniques of the present invention may be used to adjust time information to prevent problems that result from clocks that are not synchronized.

Thus, the present invention solves the disadvantages
25 of the prior art by providing a distributed cache management system that minimizes invalid cache notification events. A cache management system in a sending device processes outgoing cache notification events by adding information about the source server's
30 clock. A cache management system in the receiving device

Docket No. RSW920030224US1

then uses this information to adjust event information once the event is received. The distributed cache management system of the present invention does not depend on the particular system clock. Furthermore, the
5 present invention frees a distributed caching product from mandating an external time source.

It is important to note that while the present invention has been described in the context of a fully functioning data processing system, those of ordinary
10 skill in the art will appreciate that the processes of the present invention are capable of being distributed in the form of a computer readable medium of instructions and a variety of forms and that the present invention applies equally regardless of the particular type of
15 signal bearing media actually used to carry out the distribution. Examples of computer readable media include recordable-type media, such as a floppy disk, a hard disk drive, a RAM, CD-ROMs, DVD-ROMs, and transmission-type media, such as digital and analog
20 communications links, wired or wireless communications links using transmission forms, such as, for example, radio frequency and light wave transmissions. The computer readable media may take the form of coded formats that are decoded for actual use in a particular
25 data processing system.

The description of the present invention has been presented for purposes of illustration and description, and is not intended to be exhaustive or limited to the invention in the form disclosed. Many modifications and
30 variations will be apparent to those of ordinary skill in

Docket No. RSW920030224US1

the art. The embodiment was chosen and described in order to best explain the principles of the invention, the practical application, and to enable others of ordinary skill in the art to understand the invention for
5 various embodiments with various modifications as are suited to the particular use contemplated.
